# Nondeterministic Bigraphical Reactive Systems for Markov Decision Processes\*

### Paulius Dilkas

University of Glasgow, Glasgow, UK

**Abstract.** The abstract should briefly summarize the contents of the paper in 150–250 words.

**Keywords:** Bigraphs  $\cdot$  Probabilistic semantics  $\cdot$  Markov decision process.

### 1 Introduction

#### 1.1 Markov Decision Processes

**Definition 1** (Markov decision process). For any finite set X, let Dist(X) denote the set of discrete probability distributions over X. A Markov Decision Process is a tuple  $(S, \overline{s}, A, P, L)$ , where: S is a finite set of states and  $\overline{s} \in S$  is the initial state; A is a finite set of actions;  $P: S \times A \to Dist(S)$  is a (partial) probabilistic transition function, mapping state-action pairs to probability distributions over S;  $L: S \to 2^P$  is a labelling with atomic propositions.

**Definition 2 (rewards).** A reward structure for an MDP  $(S, \overline{s}, A, P, L)$  is a pair  $(\rho, \iota)$ , where  $\rho: S \to \mathbb{R}$  is the state reward function, and  $\iota: S \times A \to \mathbb{R}$  is the transition reward function.

#### 1.2 Bigraphs

From [4]. From PhD thesis [3]

Consider the graphical representation of a bigraph in Fig. 1. The white ellipses are the *nodes*. Each node has a type, called *control*, denoted here by the labels A, B, and C. The two white dashed rectangles represent *regions*, i.e. parents of any otherwise parentless nodes. Grey dashed rectangles are called *sites* and encode parts of the model that have been abstracted away. Nodes, sites, and regions are also known as *places*. Two places with the same parent, or two points with the same link are called *siblings*.

**Definition 3 (concrete place graph with sharing).** A concrete place graph with sharing

$$F = (V_F, ctrl_F, prnt_F) : m \to n$$

<sup>\*</sup> Supported by organization x.

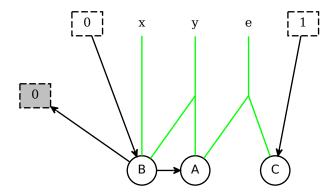

Fig. 1. An example bigraph.

is a triple having an inner interface m and an outer interface n. These index the sites and regions of the place graph, respectively. F has a finite set  $V_F \subset \mathcal{V}$ of nodes, a control map  $ctrl_F : V_F \to \mathcal{K}$ , and a parent relation

$$prnt_F \subseteq (m \uplus V_F) \times (V_F \uplus n)$$

that is acyclic, i.e.,  $(v,v) \notin prnt_F^+$  for any  $v \in V_F$ .

**Definition 4** (composition for place graphs with sharing). If  $F: k \to m$  and  $G: m \to n$  are two concrete place graphs with sharing with  $V_F \cap V_G = \emptyset$ , their composite

$$G \circ F = (V, ctrl, prnt) : k \to n$$

has nodes  $V = V_F \uplus V_G$  and control map  $ctrl = ctrl_F \uplus ctrl_G$ . Its parent relation  $prnt \subseteq (k \uplus V) \times (V \uplus n)$  is given by:

$$prnt := prnt_G^{\triangleleft} \uplus prnt_{\circ} \uplus prnt_F^{\triangleright},$$

where

$$\begin{aligned} prnt_F^{\triangleright} &= prnt_F \rhd V_F, \\ prnt_G^{\triangleleft} &= V_G \lhd prnt_G, \\ prnt_{\circ} &= (m \lhd prnt_G) \circ (prnt_F \rhd m). \end{aligned}$$

**Definition 5 (tensor product for place graphs).** If  $G_0: m_0 \to n_0$  and  $G_1: m_1 \to n_1$  are two concrete place graphs with sharing with  $V_F \cap V_G = \emptyset$ , their tensor product

$$G_0 \otimes G_1 = (V, ctrl, prnt) : m_0 + m_1 \rightarrow n_0 + n_1$$

has nodes  $V = V_{G_0} \uplus V_{G_1}$  and control map  $ctrl := ctrl_{G_0} \uplus ctrl_{G_1}$ . Its parent relation  $prnt \subseteq [(m_0 + m_1) \uplus V] \times [V \uplus (n_0 + n_1)]$  is defined as

$$prnt_{G_0} \uplus prnt_{G_1}^{(m_0,n_0)},$$

where

$$\begin{split} prnt_{G_{1}}^{(m_{0},n_{0})} = & \{(v,w) \mid (v,w) \in prnt_{G_{1}} \ and \ v,w \in V_{G_{1}} \} \\ & \uplus \{(m_{0}+i,w) \mid (i,w) \in prnt_{G_{1}}, w \in V_{G_{1}} \ and \ i \in m_{1} \} \\ & \uplus \{(v,n_{0}+i) \mid (v,i) \in prnt_{G_{1}}, v \in V_{G_{1}} \ and \ i \in n_{1} \} \\ & \uplus \{(m_{0}+i,n_{0}+j) \mid (i,j) \in prnt_{G_{1}}, i \in m_{1}, \ and \ j \in n_{1} \}. \end{split}$$

**Definition 6 (concrete link graph).** A concrete link graph

$$F = (V_F, E_F, ctrl_F, link_F) : X \to Y$$

is a quadruple having an inner face X and an outer face Y, both finite subsets of  $\mathcal{X}$ , called respectively the inner and outer names of the link graph. F has finite sets  $V_F \subset \mathcal{V}$  of nodes and  $E_F \subset \mathcal{E}$  of edges, a control map  $\operatorname{ctrl}_F : V_F \to \mathcal{K}$  and a link map

$$link_F: X \uplus P_F \to E_F \uplus Y$$
,

where  $P_F := \{(v,i) \mid i \in ar(ctrl_F(v))\}$  is the set of ports of F. Thus (v,i) is the ith port of node v. We shall call  $X \uplus P_F$  the points of F, and  $E_F \uplus Y$  its links.

The sets of points and the set of ports of a link l are defined by

$$points_F(l) := \{p \mid link_F(p) = l\}, \quad ports_F(l) := points_F(l) \setminus X.$$

An edge is *idle* if it has no points. Identities over name sets are defined by  $id_X = (\emptyset, \emptyset, \emptyset, \mathsf{Id}_X) : X \to X$ .

Definition 7 (concrete bigraph with sharing). A concrete bigraph

$$F = (V_F, E_F, ctrl_F, prnt_F, link_F) : \langle k, X \rangle \rightarrow \langle m, Y \rangle$$

consists of a concrete place graph with sharing  $F^P = (V_F, ctrl_F, prnt_F) : k \to m$  and a concrete link graph  $F^L = (V_F, E_F, ctrl_F, link_F) : X \to Y$ . We write the concrete bigraph with sharing as  $F = (F^P, F^L)$ .

Given a set of reaction rules, we refer to the configurations that a system may adopt as *states*. A bigraph with inner face  $\epsilon$  is called *ground*.

**Definition 8 (solid bigraph).** A bigraph is solid if these conditions hold:

- 1. no regions or outer names are idle (a region is called idle if it is empty);
- 2. no two sites or inner names are siblings;
- 3. the parent of every site is a node;
- 4. no outer name is linked to an inner name.

**Definition 9** (reaction rule). A reaction rule is a pair

$$R = (R: m \rightarrow J, R': m \rightarrow J),$$

sometimes written as  $R \longrightarrow R'$ , where R is the redex and R' the reactum, and R is solid. The rule generates all the ground reaction rules (r, r'), where  $r = (R \otimes \operatorname{id}_Y) \circ d$  and  $r' = (R' \otimes \operatorname{id}_Y) \circ d$  for some discrete ground parameter  $d : \epsilon \to \langle m, Y \rangle$ . The reaction relation  $\longrightarrow_{\mathsf{R}}$  over ground bigraphs is defined by

$$g \longrightarrow_{\mathsf{R}} g' \text{ iff } g = D \circ r \text{ and } g' = D \circ r'$$

for some bigraph D and some ground reaction rule (r, r') generated from R.

**Definition 10 (bigraphical reactive system (BRS)).** A bigraphical reactive system consists of a pair  $(\mathcal{B}, \mathcal{R})$ , where  $\mathcal{B}$  is a set of ground bigraphs and  $\mathcal{R}$  is a set of reaction rules defined over  $\mathcal{B}$ . It has a reaction relation

which will be written  $\longrightarrow$  when  $\mathcal{R}$  is understood.

# 2 Extensions to Bigraphs

### 2.1 Probabilistic Bigraphs

**Definition 11 (probabilistic reaction rule).** A probabilistic reaction rule R is a triple (R, R', p), sometimes written  $R \stackrel{p}{\longrightarrow} R'$ , where (R, R') is a reaction rule and  $p \in (0, 1]$  is a probability. Similarly to Definition 9, it generates a set of ground reaction rules of the form (r, r', p).

**Definition 12 (probabilistic bigraphical reactive system (PBRS)).** A probabilistic bigraphical reactive system consists of a pair  $(\mathcal{B}, \mathcal{R})$ , where  $\mathcal{B}$  is a set of ground bigraphs and  $\mathcal{R}$  is a set of probabilistic reaction rules defined over  $\mathcal{B}$ .

Let g, g' be ground bigraphs, and  $\{(r_i, r'_i, p_i)\}_{i=1}^n$  a set of ground probabilistic reaction rules, where for each  $r_i$ , there exists a bigraph  $D_i$  such that  $g = D_i r_i$ . Let  $S = \{(r_i, r'_i, p_i) \mid g' = D_i r'_i\}$  (for the same  $D_i$ ), and

$$s = \sum_{i=1}^{n} p_i.$$

Then the reaction relation is defined as

$$g \stackrel{p}{\longrightarrow} _{\mathcal{R}} g' \text{ iff } S \neq \emptyset,$$

where

$$p = \frac{1}{s} \sum_{(r,r',p') \in S} p'.$$

### 2.2 Nondeterministic Bigraphs

**Definition 13 (nondeterministic reaction rule).** Let A be a set of actions. A nondeterministic reaction rule R is a tuple (R, R', a, p), where (R, R', p) is a probabilistic reaction rule, and  $a \in A$  is an action. We also define a reaction reward function  $r: A \to \mathbb{R}$  that assigns a reward/cost to each action.

**Definition 14 (nondeterministic bigraphical reactive system (NBRS)).** A nondeterministic bigraphical reactive system consists of a pair  $(\mathcal{B}, \mathcal{R})$ , where  $\mathcal{B}$  is a set of ground bigraphs and  $\mathcal{R}$  is a set of nondeterministic reaction rules defined over  $\mathcal{B}$ .

Let g, g' be ground bigraphs,  $a \in A$  an action, and  $\{(r_i, r'_i, a, p_i)\}_{i=1}^n$  a set of ground nondeterministic reaction rules with action a, where for each  $r_i$ , there exists a bigraph  $D_i$  such that  $g = D_i r_i$ . Let  $S = \{(r_i, r'_i, a, p_i) \mid g' = D_i r'_i\}$  (for the same  $D_i$ ), and

$$s = \sum_{i=1}^{n} p_i.$$

Then the reaction relation for action a is defined as

$$g \xrightarrow[r(a)]{p} g' \text{ iff } S \neq \emptyset,$$

where

$$p = \frac{1}{s} \sum_{(r,r',a,p') \in S} p'.$$

BigraphER [5] supports defining predicates, i.e., bigraphs that are compared to every encountered state. We can associate a reward with each predicate, allowing us to assign rewards to states in a flexible and semantically meaningful way: the reward of a state is simply the sum of the rewards of all matching predicates (and 0 in case there are none).

**Proposition 1.** Any MDP can be expressed as an NBRS.

Proof. Obvious.

# 3 Implementation

Example 1. Consider an MDP  $(S, \overline{s}, A, P, L)$ , where  $S = \{s_0, s_1, s_2, s_3\}$ ,  $\overline{s} = s_0$ ,  $A = \{a, b, c\}$ , and P, L defined as follows:

$$P(s_0, a) = [s_1 \mapsto 1],$$

$$P(s_1, b) = [s_0 \mapsto 0.7, s_1 \mapsto 0.3],$$

$$P(s_1, c) = [s_2 \mapsto 0.5, s_3 \mapsto 0.5],$$

$$P(s_2, a) = [s_2 \mapsto 1],$$

$$P(s_3, a) = [s_3 \mapsto 1],$$

$$L(s_0) = \{initial\},$$

$$L(s_1) = \emptyset,$$

$$L(s_2) = \{heads\},$$

$$L(s_3) = \{tails\}.$$

Furthermore, equip it with a reward structure  $(\rho, \iota)$ , where  $\rho(s_2) = 3$ ,  $\iota(s_1, b) = 1$ , and both functions are zero everywhere else.

```
atomic ctrl S0 = 0;
atomic ctrl S1 = 0;
atomic ctrl S2 = 0;
atomic ctrl S3 = 0;
                                                         initial
big initial = S0;
big heads = S2;
big tails = S3;
action a
  react toTemp = S0 -[1.]-> S1;
  react loopH = S2 -[1.]-> S2;
                                                       toTemp
                                                             ♠.7, toInit
  react loopT = S3 -[1.]-> S3;
                                                  1
action b[1]
  react toInit = S1 -[0.7]-> S0
                                                      3, loop
  react loop = S1 -[0.3]-> S1;
{\tt end}
action c
  react toH = S1 - [0.5] -> S2;
                                           0.5, toH
                                                 0.5, to⊤
  react toT = S1 -[0.5] -> S3;
end
                                      heads
                                                  tails
begin nbrs
                                       +3
  init initial;
  rules = [ {toTemp, toInit,
    loop, toH, toT,
                                          loopH
                                                     , loopT
    loopH, loopT} ];
  preds = { initial, heads[3],
    tails };
{\tt end}
```

Listing 1.1. BigraphER code. Fig. 2. The full transition system.

The MDP can be represented as an NBRS with BigraphER code in Listing 1.1. Furthermore, the BigraphER's visualisation of the (automatically generated) transition system is in Fig. 2.

More specifically, reaction rule probabilities are represented as floating-point numbers inside the arrows (e.g. -[0.7]->), each action encompasses its reaction rules with action actionName and end. Rewards can be added to actions simply by inserting an integer enclosed in squared brackets after the action name (e.g. action b[1]). Lastly, predicate rewards have the same format, but are listed on the preds line of the begin nbrs—end block (e.g. preds = {heads[3]};).

Visually, each state is represented by a white ellipse (the starting state is highlighted with a thicker border), and each action (per state) is a grey ellipse. Text inside state ellipses lists all predicates that are satisfied by that state. Edges from actions to states are labelled with both the probability and the name of the reaction rule. Transitions from either a fully generated transition system or a simulation, labels from predicates, and state/transition rewards can be exported to the corresponding PRISM plain text formats.

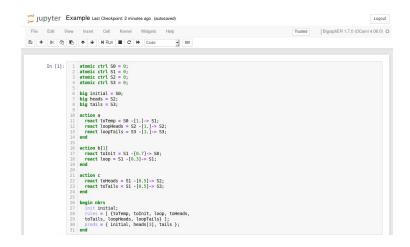

Fig. 3. The BigraphER Jupyter interface with syntax highlighting.

# 4 A Case Study in Autonomous Agents

Akin to [1] and maybe [2].

## 4.1 Collecting Objects in a Grid

Grid layout (but could be any nodes-and-edges layout, as long as it's clear how to go back home). Tracking visited/unvisited states. Each unvisited state has a probability p of containing an object. The agent returns (and stays) home after

collecting a set number of objects (easily customisable). Starting at the bottom left cell.

```
ctrl Cell = 1;
ctrl Agent = 0;
ctrl Directions = 0;
ctrl Object = 0;

atomic ctrl North = 1;
atomic ctrl East = 1;
atomic ctrl West = 1;
atomic ctrl South = 1;

atomic ctrl Visited = 1;
atomic ctrl Unvisited = 1;
```

Listing 1.2. Controls.

We begin with a list of controls in Listing 1.2. On the right hand side of each equal sign is the number of ports that each node of that control has, while the atomic keyword specifies the nodes that cannot contain other nodes. Cells represents discrete locations. They are linked to either Visited or Unvisited (initially, all except one cells are unvisited). Cells always contain Directions, and one Cell contains an Agent. The Agent may contain an Object. In order to represent multiple objects, it is convenient to put the second Object inside the first, and so on. Directions contains a subset of the four nodes, corresponding to the four possible directions of travel: North, East, West, South. We connect neighbouring Cells by linking the West node of one Cell to the East node of another (or North to South).

```
big home = Cell{v}.(Directions.(North{v1})
                                | East{v2})
                   | Agent);
big goal = Agent.Object;
big initial = Visited{v}
           || Unvisited{u}
            # bottom left
            || Cell{v}.(Directions.(North{a} | East{b})
                      | Agent.1)
            # top left
            || Cell{u}.Directions.(East{c} | South{a})
            # bottom right
            || Cell{u}.Directions.(North{d} | West{b})
            # top right
            || Cell{u}.Directions.(West{c} | South{d});
              Listing 1.3. Predicates and the initial state.
```

Next, we define two predicates: home and goal (see Listing 1.3). The former states that the agent is home if it is in the southwest corner of the grid, while the latter specifies a goal of collecting one object. A larger number of objects can be set by nesting Objects inside each other, e.g., Agent.Object.Object. Additionally, Listing 1.3 defines the initial  $2 \times 2$  grid, as described previously.

```
action north
 react goNorthToVisited =
       Visited{v}
    || Cell{v}.(Directions.(North{b} | id) | Agent)
    || Cell{v}.Directions.(South{b} | id)
    -[1.0]->
       Visited{v}
    | Cell{v}.Directions.(North{b} | id)
    || Cell{v}.(Directions.(South{b} | id) | Agent)
      @ [0, 2, 1];
 react goNorthToUnvisited =
       Visited{v} || Unvisited{u}
    || Cell{v}.(Directions.(North{b} | id) | Agent)
    || Cell{u}.Directions.(South{b} | id)
    -[1.0-p]->
       Visited{v} || Unvisited{u}
    | | Cell{v}.Directions.(North{b} | id)
    | Cell{v}.(Directions.(South{b} | id) | Agent)
      @ [0, 2, 1];
 react northObject =
       Visited{v} || Unvisited{u}
    || Cell{v}.(Directions.(North{b} | id) | Agent)
    | Cell{u}.Directions.(South{b} | id)
    -[p]->
       Visited{v} || Unvisited{u}
    || Cell{v}.Directions.(North{b} | id)
    || Cell{v}.(Directions.(South{b} | id)
              | Agent.Object)
      @ [0, 2, 1];
end
```

Listing 1.4. The action of going north.

Then, we have an action for each of the four directions, each with three reaction rules: one for going to an already visited cell, one for visiting a cell for the first time, and one for visiting a cell for the first time and finding an object. We will use the rules for going north in Listing 1.4 as an example. When going to an already visited cell, the Agent simply traverses a link between the North node of its previous Cell and the corresponding South node. As this is the only reaction rule for this situation, its probability is 1. When going to an unvisited node, we collect an Object with probability p, or make the transition without

getting an Object with probability 1-p. Regardless, the Cell changes its link from Unvisited to Visited.

```
react stayHome =
   Cell{v}.(Directions.(North{v1} | East{v2}) | goal)
   -[1.0]->
   Cell{v}.(Directions.(North{v1} | East{v2}) | goal);
```

Listing 1.5. Reaction rule to stay home if a required number of objects is acquired.

Lastly, we have three actions for after the agent acquires the specified number of objects: two for going home west or south (since these are the two directions necessary and sufficient to reach home), and one for staying home. The former type of actions have two reaction rules each, depending on whether the destination cell is visited or not. They are just like the rules in Listing 1.4, except every mention of Agent is replaced with goal. The rule to stay home is quite straightforward and is in Listing 1.5.

### 4.2 Layers of Abstraction

**Listing 1.6.** The initial map: three consecutive cells, the midmost of which has an inner room.

```
action room
  react openDoor =
    Cell{w}.(Agent | Node{n}.1 | id)
    -[p] -> /x /y /z /a /b /c /d
    Cell{w}.(Agent | Node{n}.(
      # top left
        Cell{n}.Directions.(East{a} | South{b})
      # top right
      | Cell{x}.Directions.(West{a} | South{c})
      # bottom left
      | Cell{y}.Directions.(North{b} | East{d})
      # bottom right
      | Cell{z}.Directions.(North{c} | West{d}))
      | id);
  react closedDoor =
    Cell{w}.(Agent | Node{n}.1 | id)
    -[1.0-p] - /x /y /z /b /c /d
    Cell{w}.(Agent | Node{n}.(
      # top left
```

```
Cell{n}.Directions.(South{b})
# top right
| Cell{x}.Directions.(South{c})
# bottom left
| Cell{y}.Directions.(North{b} | East{d})
# bottom right
| Cell{z}.Directions.(North{c} | West{d}))
| id);
end
```

Listing 1.7. Two ways to generate a room, leaving one door either open or closed.

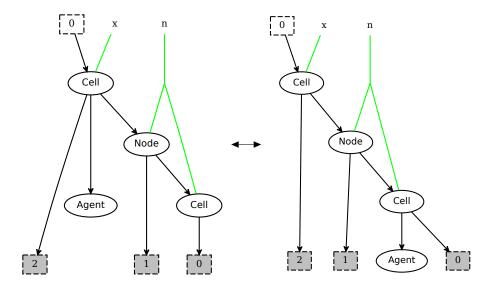

Fig. 4. Left to right: the reaction rule to go inside; right to left: the reaction rule to go outside.
